

Learning Outcomes

1. Describe the history and evolution of programming languages
2. Categorize programming languages based on principal characteristics
3. Describe the fundamental elements of a programming language
4. Compare and contrast the 4 generations of programming languages
5. Identify a basic programming elements in simple computer programs

1st Generation

- ❑ The first programming language was the machine code itself, combinations of 1s and 0s
- ❑ As close to the machine as it gets, the machine's own language.
 - Specific to particular CPU architectures, a program written for one type of processor can only work on that type and nothing else
 - Hard to do, impossible for large programs
 - Not for humans... well not for most humans
 - This is how the first programs were programmed on the first computers
- ❑ The source code and the executable code are the same
- ❑ No compiler needed because no translation is required
- ❑ We don't do this anymore, not even in micro-controller programming

Binary for
"This program
cannot be run
in DOS mode"

2nd Generation

- ❑ 1st generation was hard, too hard to create large programs
- ❑ The solution was to “name” the binary instructions using short but easier to remember “**mnemonics**” like...
 - add, sub, mov, call, push, pop, jmp, cmp
- ❑ Such programming languages are called **assembly languages**
- ❑ The program that translates assembly language into machine code is called **assembler**
 - Executable programs can be converted back to assembly using **disassemblers**
- ❑ Barely above 1s and 0s but much easier
 - We still write programs in assembly, parts of highly optimized programs like games, real-time systems, micro-controller programs etc.

The
beginning
of
java.exe
in
**assembly
language**

3rd Generation

- ❑ As programs became more complicated the need for programming languages closer to “human” languages grew
- ❑ Software development processes evolved with new constructs, better ways of creating complex, robust, easier to maintain programs
- ❑ The program that translates source code of a 3rd generation language into machine language is called a **compiler**
 - Only the compiler designer needs to know machine language!
- ❑ 3rd generation programming languages were a huge leap in computer science
- ❑ Also called **high-level languages**

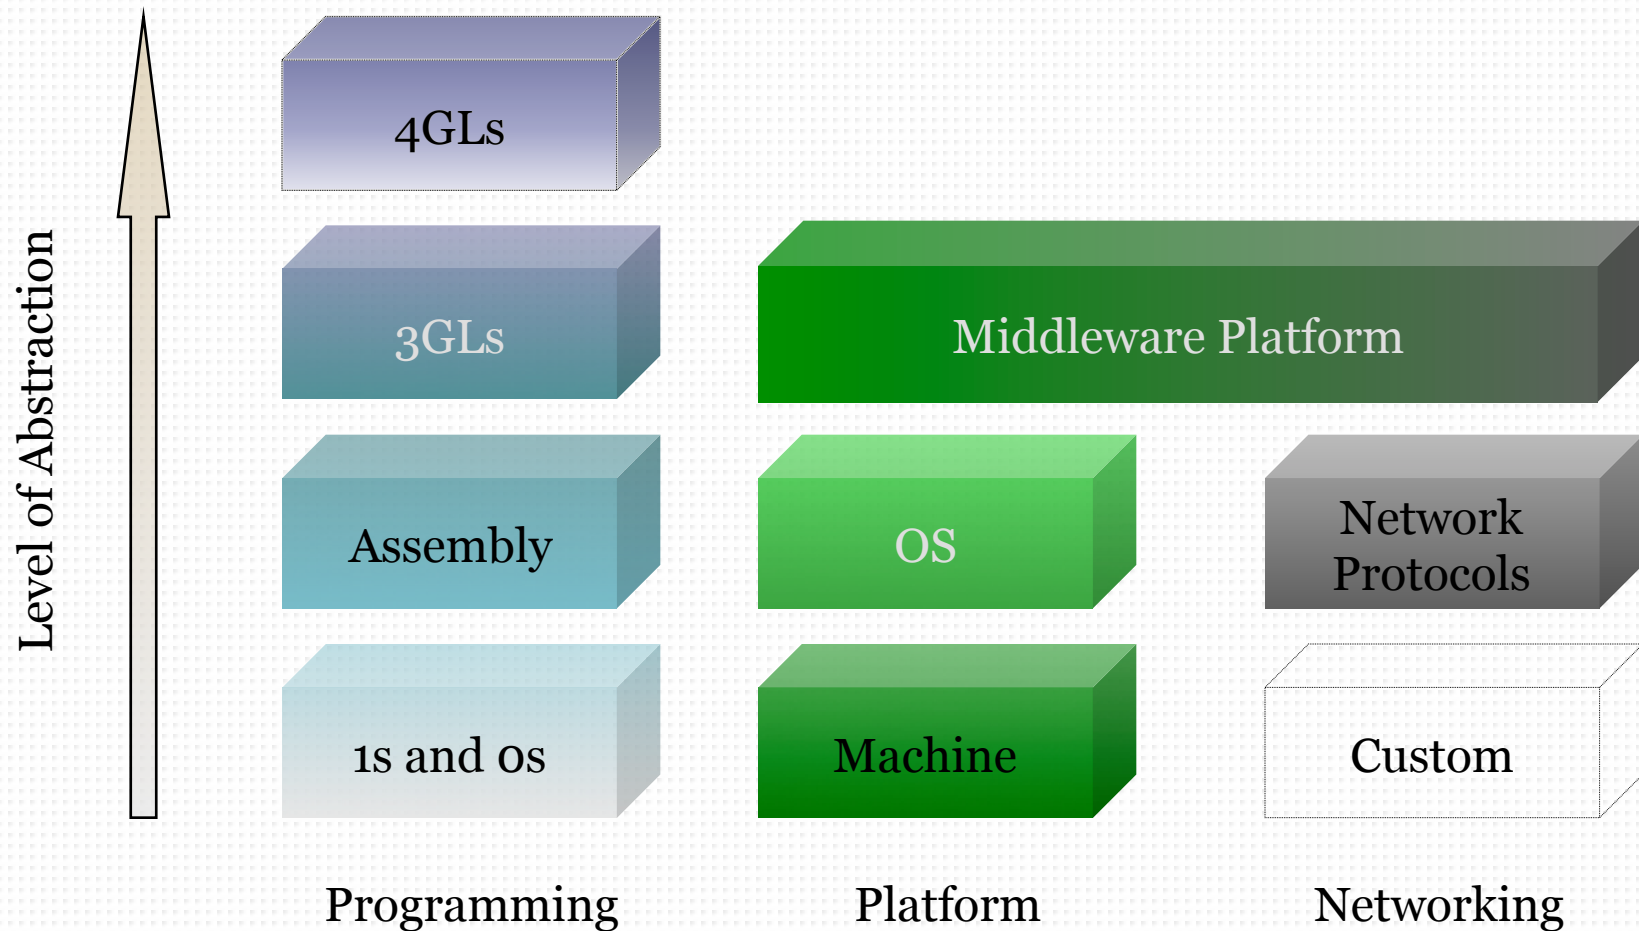

3rd Generation Programming Languages

- ❑ Modern languages
 - Java
 - C#, Visual Basic.NET
 - C++
 - C
 - Delphi
 - Visual Basic
 - Pascal
 - PHP
- ❑ Legacy languages, still in use today
 - COBOL
 - FORTRAN
 - Ada

4th and 5th Generation Languages

- ❑ In 3rd generation languages you still write commands telling the computer what to do.
- ❑ How can one improve that?
 - By telling the computer what you want instead
 - SQL (Structured Query Language) and FoxPro for database development
 - Programs that generate other programs, like auto code gen. in some IDEs
 - These can be considered 4th generation languages, but true, general purpose 4th gen languages are still a research area
- ❑ 5th generation languages – solve problems by specifying constraints, not by giving an algorithm, examples: Prolog, Datalog
 - Artificial intelligence, logic programming
 - Example applications: Medical diagnosis, robot planning, music composition

Evolution in Computing

So what exactly is a programming language?

It is just a language like any other...!

Example program written in Java

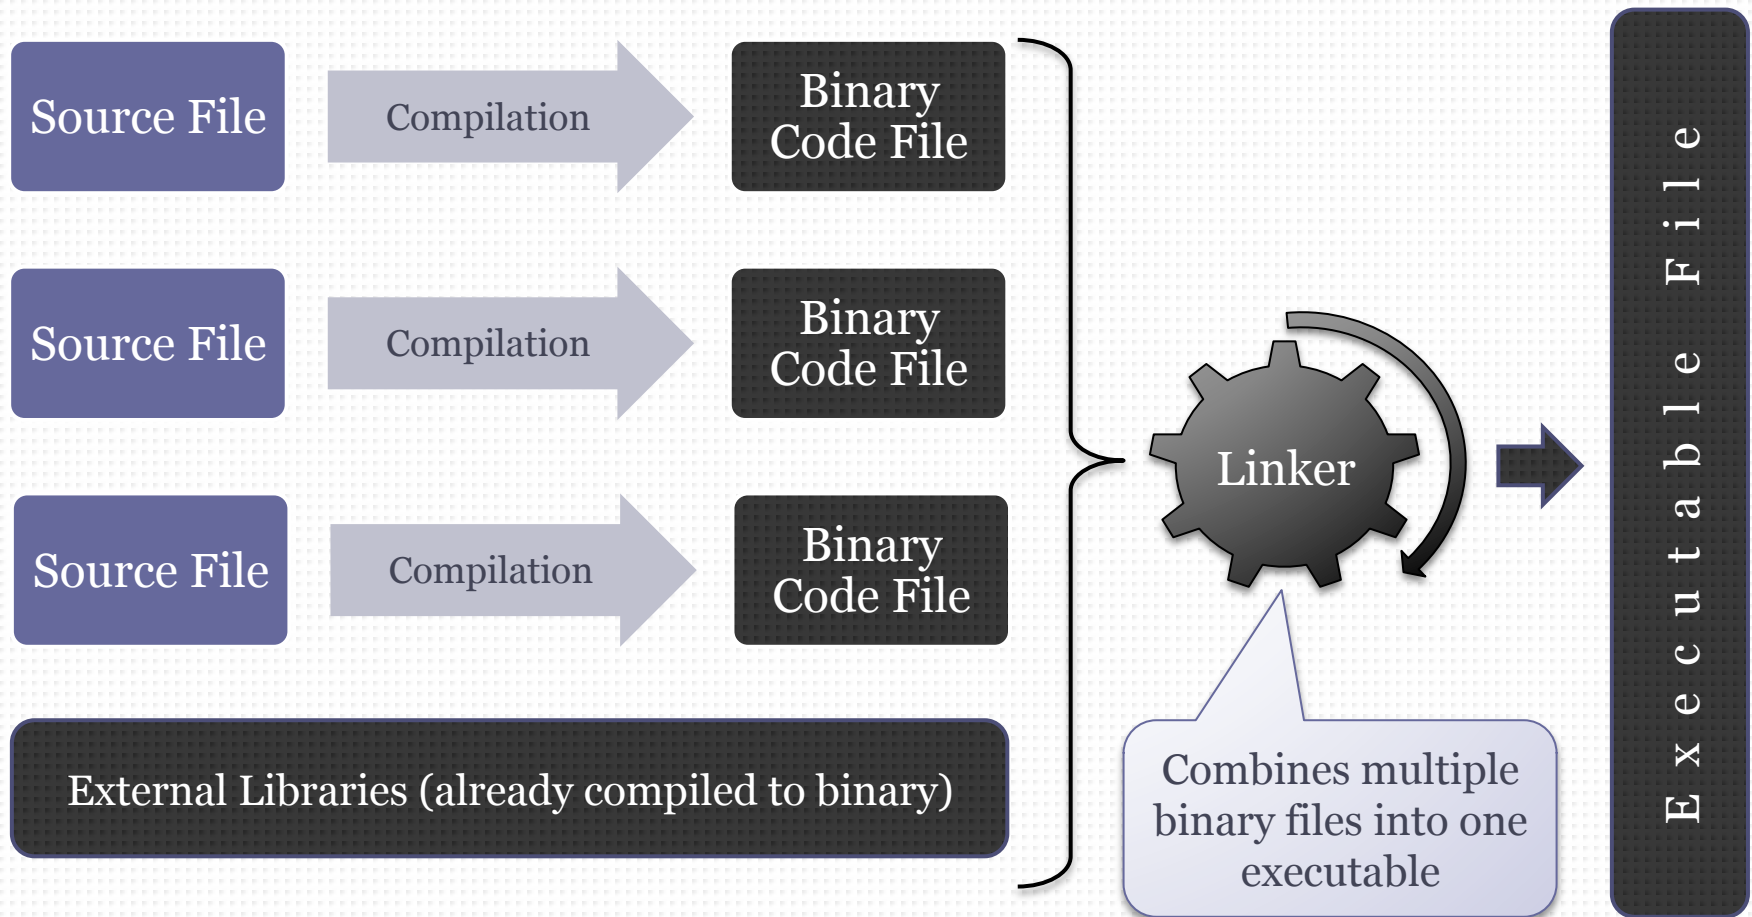

```
package sheridan;

public class Program {
    public static void main(String[] args) {
        // Write a message to the screen
        System.out.println("Hello PROG10082 class");
        int result = 2 + 2;
        System.out.println("The answer is " + result);
    }
}
```

Just a Language

- ❑ A programming language is a lot like any other language (e.g. English, Spanish, Punjabi) but **simpler** and more precise
- ❑ **Alphabet**: letters, numbers, math symbols, parenthesis and brackets, semi-colon, slashes, spaces, tabs
 - Largely the same as the English alphabet
- ❑ **Vocabulary**: the words that have a defined meaning.
 - A programming language has a MUCH SMALLER vocabulary
 - Words in a programming language vocabulary are called “**reserved words**” or “**keywords**”
 - We can **invent new words** in our programs but we must first **declare** them and define them. They cannot be the same as the reserved words.
- ❑ **Syntax**: the way words are put together to convey meaning
 - Very important to a programming language and very exact. The computer only understands exact rules

Many Source Files to One Executable

Review: Source Code

- ❑ What we write and what the compiler translates
- ❑ Source code is stored (saved) in **source files**
 - These are **text files**
- ❑ Source files are stored (saved) on storage devices like a hard drive
- ❑ Source code is a set of commands or instructions written in a programming language
- ❑ A **compiler** reads source files, processes all the commands and translates them into an **executable file** that contains machine code
 - The process of transforming a source file into an binary file is called **compilation**, or **compiling**
- ❑ A **program** is a collection of source files
